

Abstract of the Disclosure

System and Method for Remotely Modifying Software on a Machine

A system and method for updating software stored in control modules on a remotely-located machine. The current machine configuration is stored in a machine and a remote system, and the configuration in the remote system is monitored to determine if an update, such as an enhancement, "bug" fix, or new version, is available. If so, the owner of the machine is remotely notified and offered the update. If the owner accepts, the update is relayed to the machine system and flashed into the appropriate control module.
